# A comparison of video laryngoscopy and direct laryngoscopy in critically ill patients

Yang Zhao<sup>1</sup>, Qian Wang<sup>2\*</sup> and Bin Zang<sup>1\*</sup>

### To the Editor,

We read the article "Video versus direct laryngoscopy in critically ill patients: an updated systematic review and meta-analysis of randomized controlled trials" by Araújo et al. [1] with great interest. Although the article is wellwritten, certain parts merit further discussion.

Following the authors' search strategy, our reevaluation revealed that the study omitted several randomized controlled trials (RCTs) that met the criteria, including Mo et al. [2], Shukla et al. [3], Ilbagi et al. [4], Grensemann et al. [5], Kim et al. [6], Silverberg et al. [7]. These six additional RCTs increased the total patient count to 4532, with 2276 in the video laryngoscopy (VL) group and 2256 in the direct laryngoscopy (DL) group. We extracted data from the newly included RCTs and analyzed successful intubations on the first attempt using STATA 16.0 (Stata Corp., College Station, TX, USA). The meta-analysis result suggests that VL significantly enhances the first-attempt success rate compared to DL (RR, 1.12; 95% CI 1.05, 1.19; P < 0.05) (Fig. 1).

In light of the new result regarding the first-attempt success rate, we conducted a Trial Sequential Analysis (TSA) analysis. The two-sided Type I error was set at 5%, and a power of 80% was chosen to calculate the required information size (RIS) for the analysis. The incidence in the control arm was estimated through the metaanalysis. The results showed that the blue cumulative Z-curve, created using a random-effects model, crossed the traditional and TSA boundaries and reached the RIS. Consequently, this finding confirmed the improved first-attempt success rate with VL (Fig. 2).

By expanding the sample size and increasing the number of studies, our analysis provided more comprehensive evidence-based evidence.
