We read with interest the article by Nascimento and colleagues [1] on fresh frozen plasma (FFP) in massive bleedings. We fully agree with their conclusion when they say that we need immediately available universal donor AB plasma.

Hemorrhagic shock is the primary cause of avoidable mortality in combatants. Data from the recent US army war experience show clearly that in cases of massive transfusion the transfusion policy strongly impacts mortality. Namely, for massive bleeding the ratio between red blood cells and clotting factors should be close to the composition of whole blood [2].

Plasma is thus essential for massive transfusions. But FFP use is impractical in uncertain environments such as a battlefield. During military operations, refrigerated transportation and storage are logistical problems. Thawing of FFP takes a long time, with an important loss of plasma in austere environments. For example, Mabry and colleagues [3] report that, during the Mogadishu urban battle, the available FFP was stored in bags that fractured one-third of the time upon thawing.

For these reasons, the French army has used freezedried and secured plasma (FDSP) since 1994. Plasma separated from fresh blood of at least ten donors is lyophilized to produce FSDP. Blood type selection allows the dilution and neutralization of natural anti-A and anti-B hemagglutinins. This FDSP is thus compatible with any blood type. In addition, FDSP is shelf-stable in ambient temperatures for 2 years and easily rehydrated with 200 ml of water for injections in less than 3 minutes, allowing immediate provision with the first packed red blood cells [4].

FDSP contains all clotting factors and proteins. After more than 2 years storage at ambient temperature, the fibrinogen and clotting factor levels of FDSP are equivalent to FFP [4].

The securization process is quarantine (i.e. the plasma is held until the donor returns and is retested after a period that is longer than the window period of known viruses). Plasma as FDSP is thus a logistically superior product, without compromising hemostatic properties, quickly available in cases of emergency for any blood type.

## Authors' response

Bartolomeu Nascimento Jr, Jeannie Callum and Sandro B Rizoli

We thank Daban and colleagues for their insightful observations and agree with the comments on the challenges to using AB FFP in trauma. Products such as freeze-dried plasma or lyophilized plasma are appealing for trauma resuscitation since they have many of the characteristics of an ideal resuscitation fluid for bleeding/ coagulopathic patients. Such an ideal fluid would be easy to prepare and rapid to administer, contain all clotting factors, not require blood typing and matching, be free of infectious and immunological risks and have a long shelf life. Concerning volume, it is unclear whether the benefit of early and aggressive FFP transfusion in massive traumatic bleeding is related to either clotting factor or volume replacement with reduced crystalloid exposure. Since most trauma patients are hypovolemic, large volumes are often advantageous, but in circumstances where circulatory overload is a concern, the use of small volume clotting factor concentrates, including freezedried plasma, would be superior.

We lack experience with lyophilized plasma, which to our knowledge is available only to military personnel of some countries. Historically it was implicated in hepatitis epidemics during the Korean War, but safer preparations are now available and the interest in this product is growing, particularly over the past few years. Recent experience with this product comes from the battlefield, but mostly from animal models [4-6], in which lyophilized plasma was found to be equivalent to FFP in correcting coagulopathy [5,6]. We agree that further clinical studies with this product are needed.
